

Object – Oriented Programming

Week 7

Inheritance

Weng Kai

Inheritance

Reusing the implementation

- Composition: construct new object with existing objects
- It is the relationship of “has-a”

Composition

- Objects can be used to build up other objects
- Ways of inclusion
 - Fully
 - By reference
- Inclusion by reference allows sharing
- For example, an Employee has a
 - Name
 - Address
 - Health Plan
 - Salary History
 - Collection of Raise objects
 - Supervisor
 - Another Employee object!

Composition in action

Classes

Employee

— Name

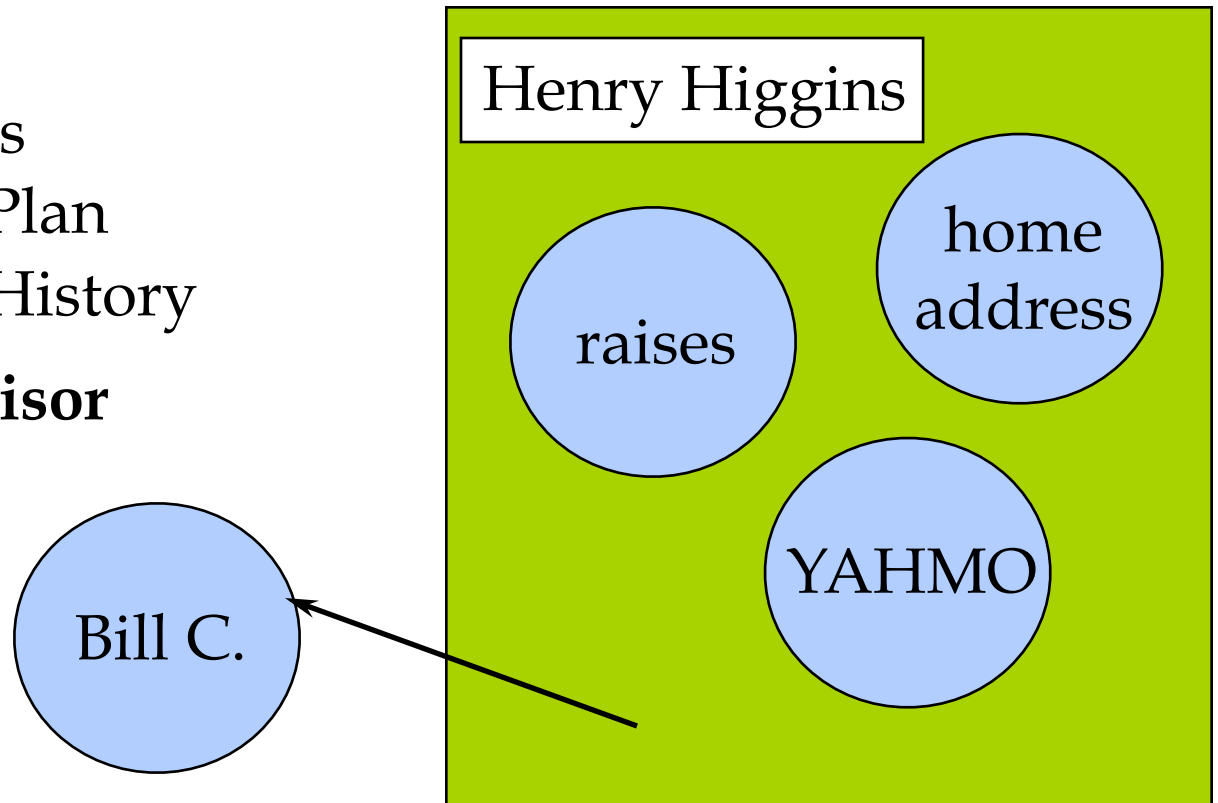

— Address

— HealthPlan

— Salary History

— **Supervisor**

Instances

Example

```
class Person { ... };  
class Currency { ... };  
class SavingsAccount {  
public:  
    SavingsAccount( const char* name,  
                    const char* address, int cents );  
    ~SavingsAccount();  
    void print();  
private:  
    Person m_saver;  
    Currency m_balance;  
};
```

Example...

```
SavingsAccount::SavingsAccount ( const  
    char* name, const char* address,  
    int cents ) : m_saver(name, address),  
    m_balance(0, cents) {}
```

```
void SavingsAccount::print() {  
    m_saver.print();  
    m_balance.print();  
}
```

Embedded objects

- All embedded objects are initialized
 - The default constructor is called if
 - you don't supply the arguments, and there is a default constructor (or one can be built)
- Constructors can have initialization list
 - any number of objects separated by commas
 - is optional
 - Provide arguments to sub-constructors
- Syntax:

```
name ( args ) [ ':' init-list ] '{ '
```

Question

- If we wrote the constructor as (assuming we have the set accessors for the sub-objects):

```
SavingsAccount::SavingsAccount ( const char* name,  
    const char* address, int cents ) {  
    m_saver.set_name( name );  
    m_saver.set_address( address );  
    m_balance.set_cents( cents );  
}
```

- Default constructors would be called

Public vs. Private

- It is common to make embedded objects private:
 - they are part of the underlying implementation
 - the new class only has part of the public interface of the old class
- Can embed as a public object if you want to have the entire public interface of the subobject available in the new object:

```
class SavingsAccount {  
    public:  
        Person m_saver;    ... };    // assume  
        Person class has set_name()  
    SavingsAccount  account;  
    account.m_saver.set_name("Fred" );
```

Reusing the interface

- Inheritance is to take the existing class, clone it, and then make additions and modifications to the clone.

Inheritance

- Language implementation technique
- Also an important component of the OO design methodology
- Allows sharing of design for
 - Member data
 - Member functions
 - Interfaces
- Key technology in C++

Inheritance

- The ability to define the behavior or implementation of one class as a superset of another class

DoME

- is an application that lets us store information about CDs and DVDs. We can
 - enter information about CDs and DVDs
 - search, for example, all CDs in the database by a certain artist, or all DVDs by a given director

CD

- the title of the album;
- the artist (name of the band or singer);
- the number of tracks on the CD;
- the total playing time;
- a 'got it' flag that indicates whether I own a copy of this CD; and
- a comment (some arbitrary text).

DVD

- the title of the DVD;
- the name of the director;
- the playing time (we define this as the playing time of the main feature);
- a ‘got it’ flag that indicates whether I own a copy of this DVD; and
- a comment (some arbitrary text)

The DoME example

"Database of Multimedia Entertainment"

- stores details about CDs and DVDs
 - CD: title, artist, # tracks, playing time, got-it, comment
 - DVD: title, director, playing time, got-it, comment
- allows (later) to search for information or print lists

DoME classes

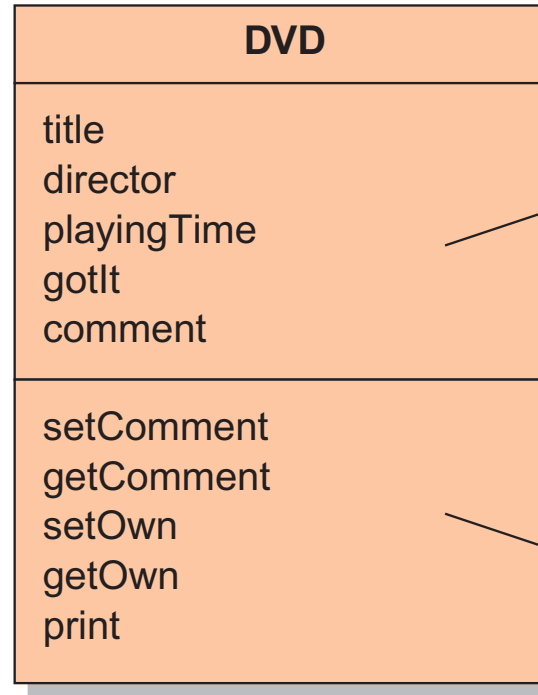

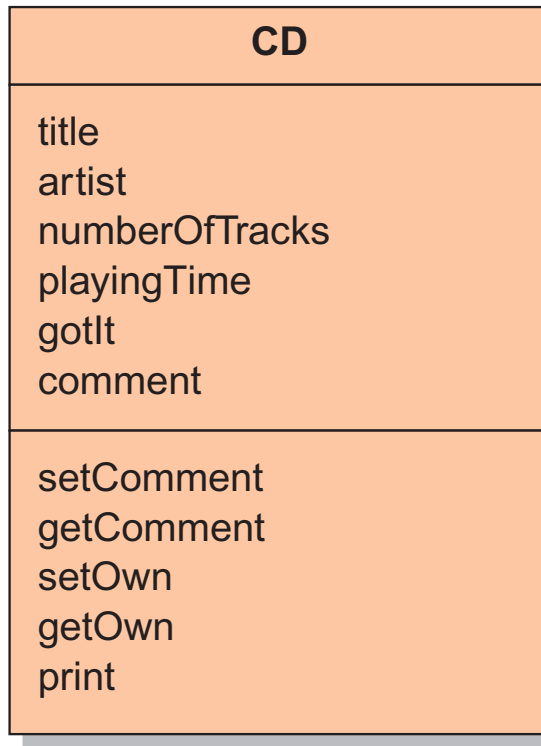

:CD

title	<input type="text"/>
artist	<input type="text"/>
#tracks	<input type="text"/>
playing time	<input type="text"/>
got it	<input type="text"/>
comment	<input type="text"/>

:DVD

title	<input type="text"/>
director	<input type="text"/>
playing time	<input type="text"/>
got it	<input type="text"/>
comment	<input type="text"/>

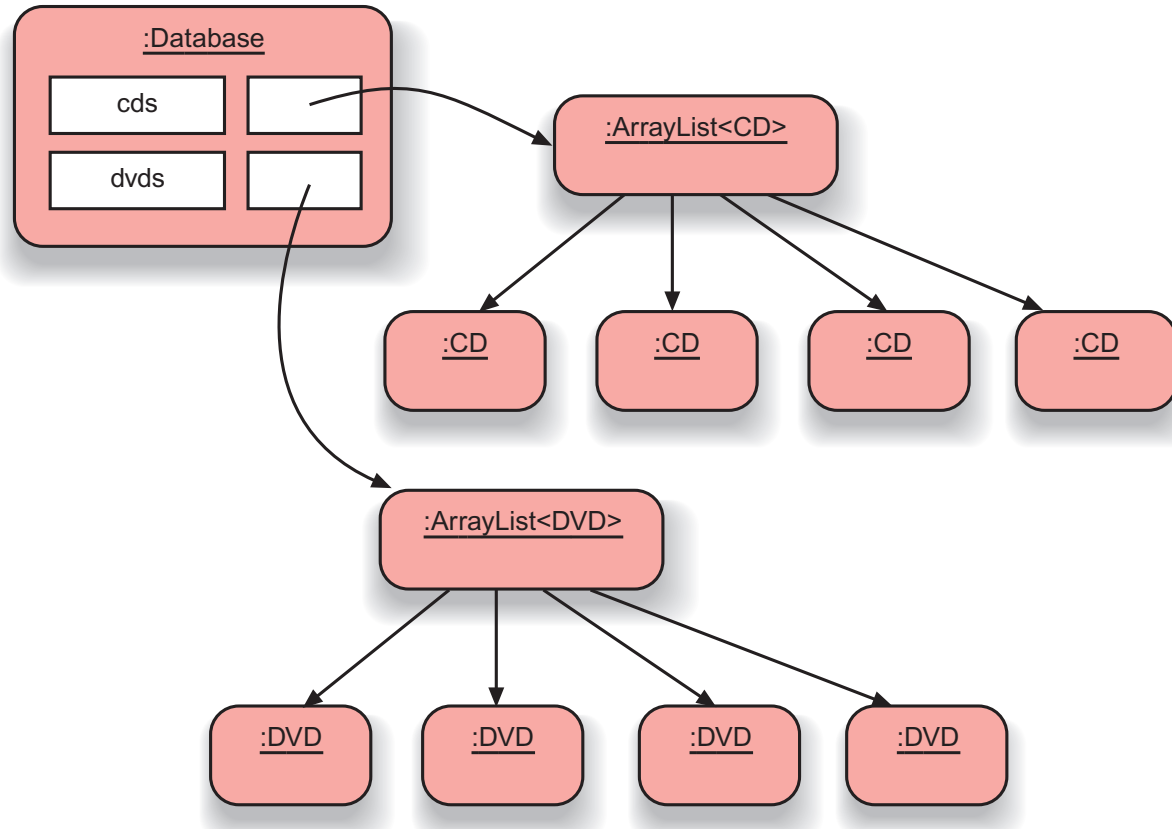

Class diagram

*top half
shows fields*

*bottom half
shows methods*

Object Model

Class diagram

source code

```
public class Database
{
    private ArrayList<CD> cds;
    private ArrayList<DVD> dvds;
```

```
public void addCD(CD theCD)
{
    cds.add(theCD);
}
```

```
public void addDVD(DVD theDVD)
{
    dvds.add(theDVD);
}
```

```
public void list()
{
    // print list of CDs
    for(CD cd : cds) {
        cd.print();
        System.out.println();
    }

    // print list of DVDs
    for(DVD dvd : dvds) {
        dvd.print();
        System.out.println();
    }
}
```

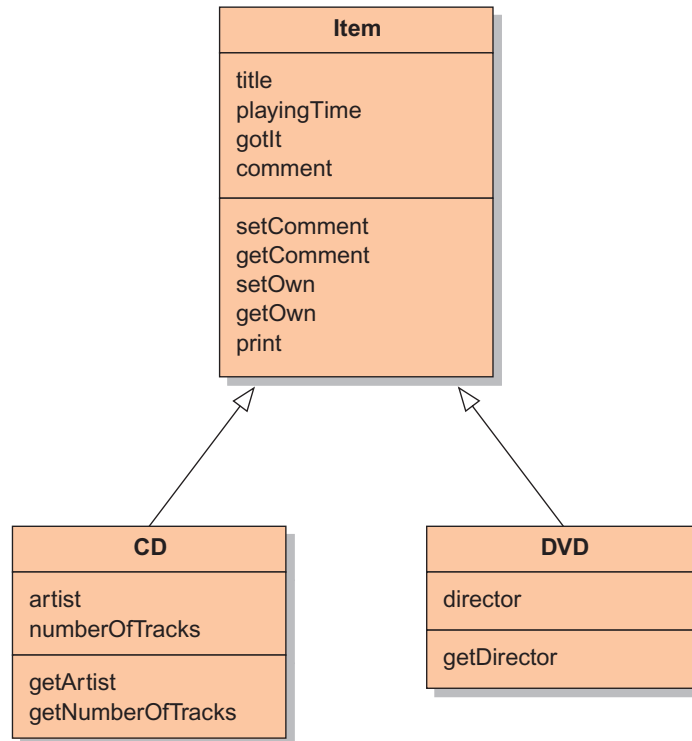

Critique of DoME

- code duplication
 - CD and DVD classes very similar (large part are identical)
 - makes maintenance difficult/more work
 - introduces danger of bugs through incorrect maintenance
- code duplication also in Database class

Discuss

- The CD and DVD classes are very similar. In fact, the majority of the classes' source code is identical, with only a few differences
- In the Database class. We can see that everything in that class is done twice – once for CDs and once for DVDs
 - What if we'd add new types of media?

Solution - inheritance

- Inheritance allows us to define one class as an extension of another.

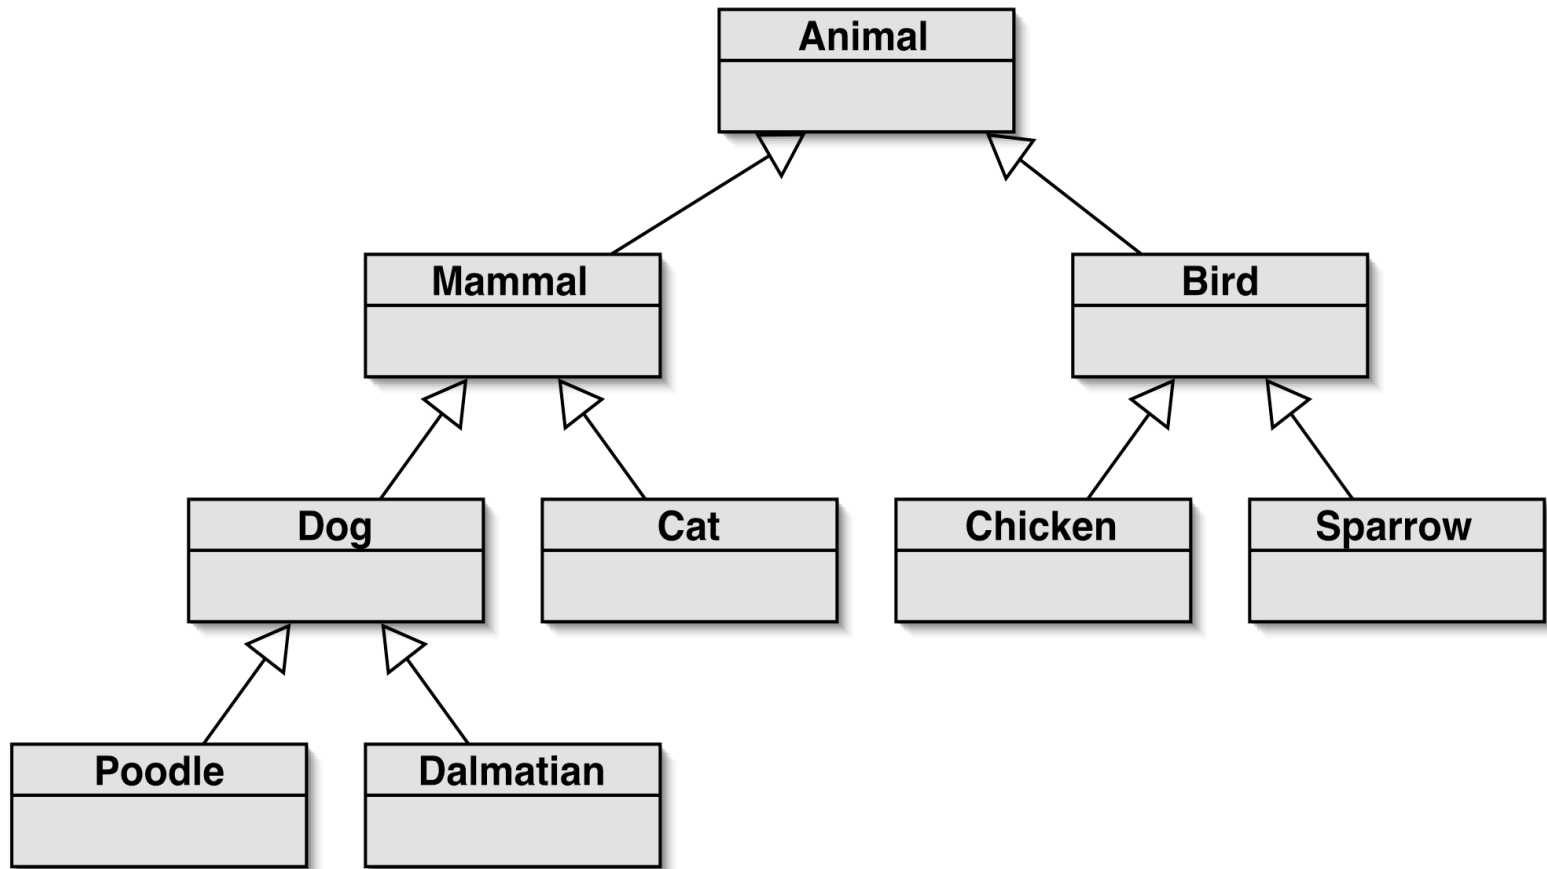

Class diagram

Using inheritance

- define one **superclass** : Item
- define **subclasses** for Video and CD
- the superclass defines common attributes
- the subclasses **inherit** the superclass attributes
- the subclasses add own attributes

Inheritance hierarchies

Inheritance

```
class Item
{
    ...
}
```

no change here

change
here

```
class CD : public Item
{
    ...
}
```

```
class DVD : public Item
{
    ...
}
```

Database v2.0

```
public void addItem(Item theItem)
{
    items.add(theItem);
}

/**
 * Print a list of all currently stored items to
 * the text terminal.
 */
public void list()
{
    for(Item item : items) {
        item.print();
        System.out.println();    // empty line between items
    }
}
```

```
public void addCD(CD theCD)
{
    cds.add(theCD);
}
```

```
public void addItem(Item theItem)
{
    items.add(theItem);
}
```

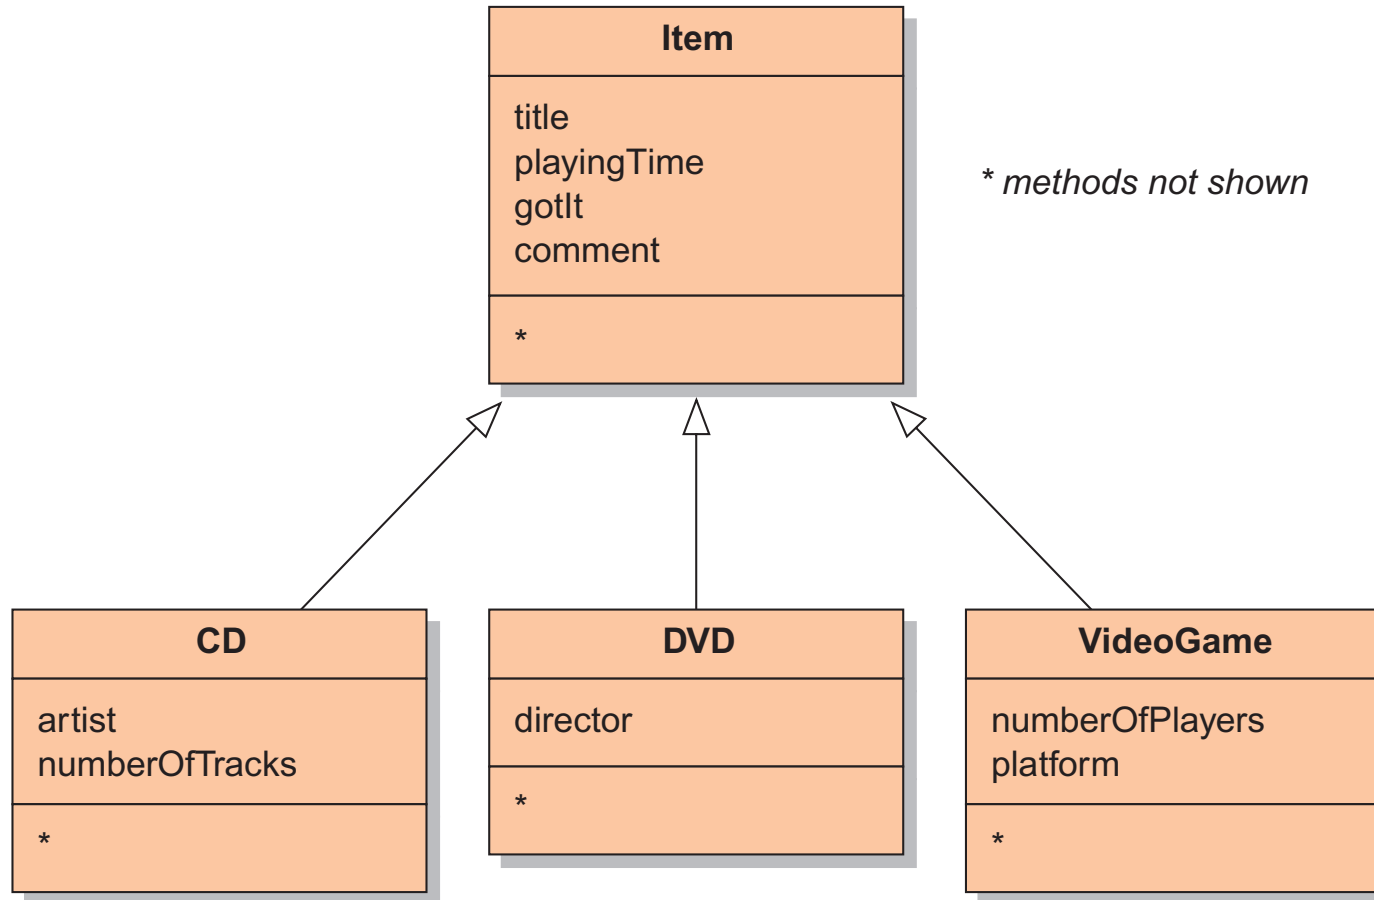

```
public void addDVD(DVD theDVD)
{
    dvds.add(theDVD);
}
```

```
public void list()
{
    // print list of CDs
    for(CD cd : cds) {
        cd.print();
        System.out.print("\n");
    }

    // print list of DVDs
    for(DVD dvd : dvds) {
        dvd.print();
        System.out.println();
    }
}
```

```
public void list()
{
    for(Item item : items) {
        item.print();
        System.out.println();
    }
}
```

Adding other item types

Deeper hierarchies

Advantages of inheritance

- Avoiding code duplication
- Code reuse
- Easier maintenance
- Extendibility

Inheritance

- The ability to define the behavior or implementation of one class as a ***superset*** of another class

Inheritance

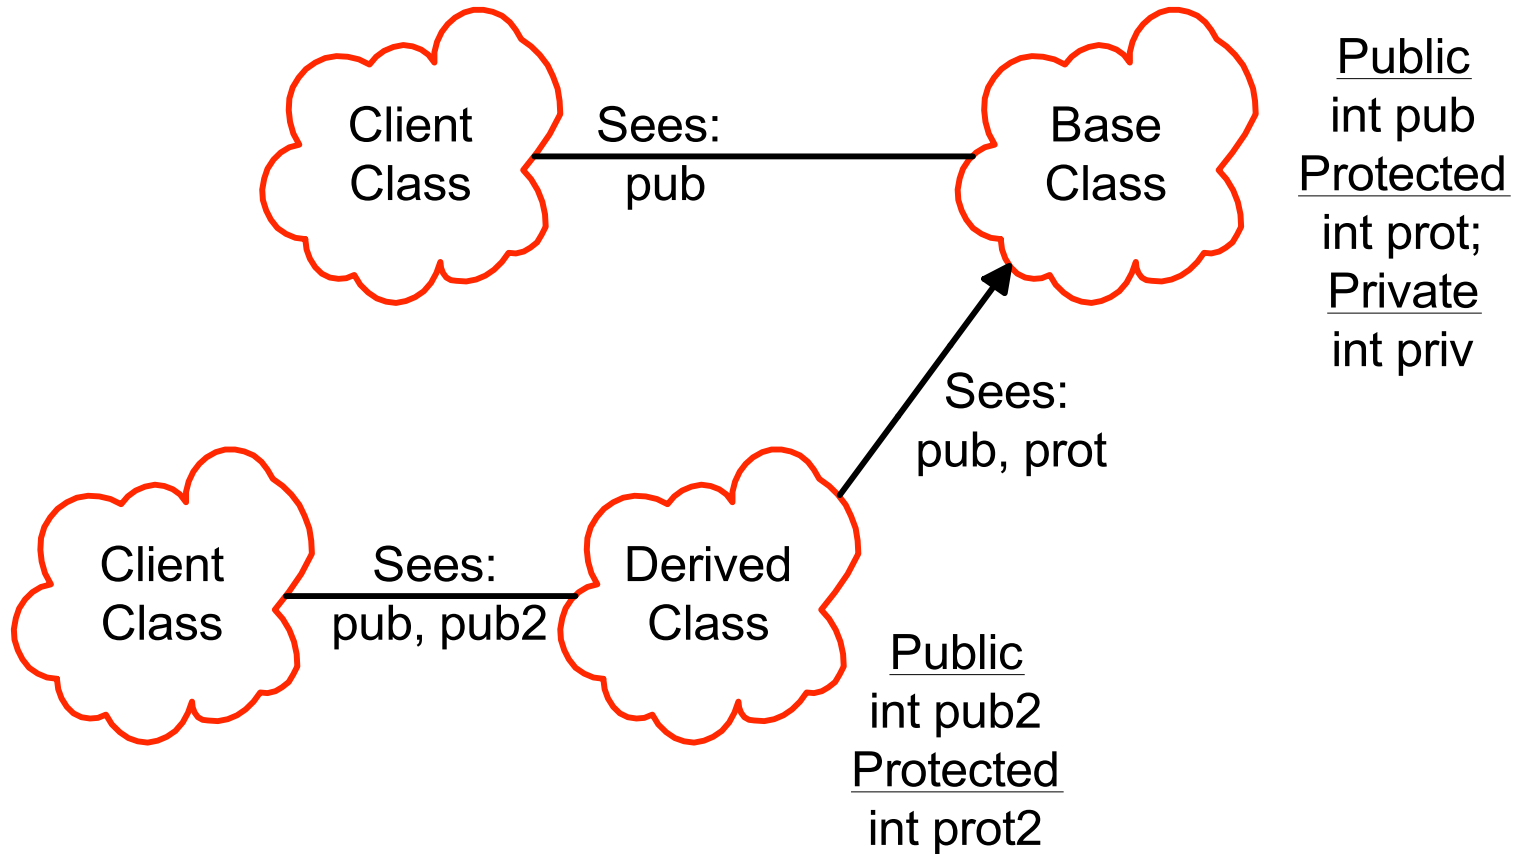

- **Class relationship: Is-A**

Base Class
Super
Parent

Derived Class
Sub
Child

Scopes and access in C++

Declare an Employee class

```
class Employee {  
public:  
    Employee( const std::string& name,  
              const std::string& ssn );  
  
    const std::string& get_name() const;  
    void print(std::ostream& out) const;  
    void print(std::ostream& out, const  
              std::string& msg) const;  
protected:  
    std::string m_name;  
    std::string m_ssn;  
};
```

Constructor for Employee

```
Employee::Employee( const string& name,  
                    const string& ssn )  
    : m_name(name), m_ssn( ssn)  
{  
    // initializer list sets up the values!  
}
```

Employee member functions

```
inline const std::string& Employee::get_name() const
{
    return m_name;
}

inline void Employee::print( std::ostream& out )
const {
    out << m_name << endl;
    out << m_ssn << endl;
}

inline void Employee::print(std::ostream& out, const
std::string& msg) const {
    out << msg << endl;
    print(out);
}
```

Now add Manager

```
class Manager : public Employee {  
public:  
    Manager(const std::string& name,  
            const std::string& ssn,  
            const std::string& title);  
    const std::string title_name() const;  
    const std::string& get_title() const;  
    void print(std::ostream& out) const;  
private:  
    std::string m_title;  
};
```

Inheritance and constructors

- Think of inherited traits as an embedded object
- Base class is mentioned by class name

```
Manager::Manager( const string& name, const string&
ssn, const string& title = "" )
    :Employee(name, ssn), m_title( title )
{
}
```

More on constructors

- Base class is always constructed first
- If no explicit arguments are passed to base class
 - Default constructor will be called
- Destructors are called in exactly the reverse order of the constructors.

Manager member functions

```
inline void Manager::print( std::ostream& out )
    const {
        Employee::print( out );          // call the base
        class print
        out << m_title << endl;
    }

inline const std::string& Manager::get_title() const
    {
        return m_title;
    }

inline const std::string Manager::title_name() const
    {
        return string( m_title + ": " + m_name ); //
        access base m_name
    }
```

Uses

```
int main () {
    Employee bob( "Bob Jones", "555-44-0000" );
    Manager bill( "Bill Smith", "666-55-1234", "Important
Person" );

    string name = bill.get_name();    // okay Manager
inherits Employee
    //string title = bob.get_title();    // Error -- bob is
an Employee!
    cout << bill.title_name() << '\n' << endl;
    bill.print(cout);
    bob.print(cout);
    bob.print(cout, "Employee:");
    //bill.print(cout, "Employee:");    // Error hidden!
}
```

Name Hiding

- If you redefine a member function in the derived class, all other overloaded functions in the base class are inaccessible.
- We'll see how the keyword `virtual` affects function overloading next time.

What is not inherited?

- Constructors
 - synthesized constructors use memberwise initialization
 - In explicit copy ctor, explicitly call base-class copy ctor or the default ctor will be called instead.
- Destructors
- Assignment operation
 - synthesized `operator=` uses memberwise assignment
 - explicit `operator=` be sure to explicitly call the base class version of `operator=`
- Private data is hidden, but still present

Access protection

- Members
 - Public: visible to all clients
 - Protected: visible to classes derived from self
(and to friends)
 - Private: visible only to self and to friends!
- Inheritance
 - Public: `class Derived : public Base ...`
 - Protected: `class Derived : protected Base ...`
 - Private: `class Derived : private Base ...`
 - default

How inheritance affects access

Suppose class B is derived from A. Then

Base class member access specifier

Inheritance Type (B is)	public	protected	private
public A	public in B	protected in B	hidden
private A	private in B	private in B	hidden
protected A	protected in B	protected in B	hidden

When is protected not protected?

- When your derived classes are ill-behaved!
- Protected is public to all derived classes
- For this reason
 - make member *functions* protected
 - keep member *variables* private

Conversions

- Public Inheritance should imply substitution
 - If *B isa A*, you can use a B anywhere an A can be used.
 - if B isa A, then everything that is true for A is also true of B.
 - Be careful if the substitution is not valid!

D is derived from B		
D	\Rightarrow	B
D*	\Rightarrow	B*
D&	\Rightarrow	B&

Up-casting

- Is to regard an object of the derived class as an object of the base class.
- It is to say: Students are human beings. You are students. So you are human being.

Upcasting

- Upcasting is the act of converting from a Derived reference or pointer to a base class reference or pointer.

Upcasting examples

```
Manager pete( "Pete", "444-55-6666", "Bakery");  
Employee* ep = &pete; // Upcast  
Employee& er = pete;  // Upcast
```

- Lose type information about the object:
 `ep->print(cout);` // prints base class version

A drawing program

Operations

- render
- move
- resize

Data

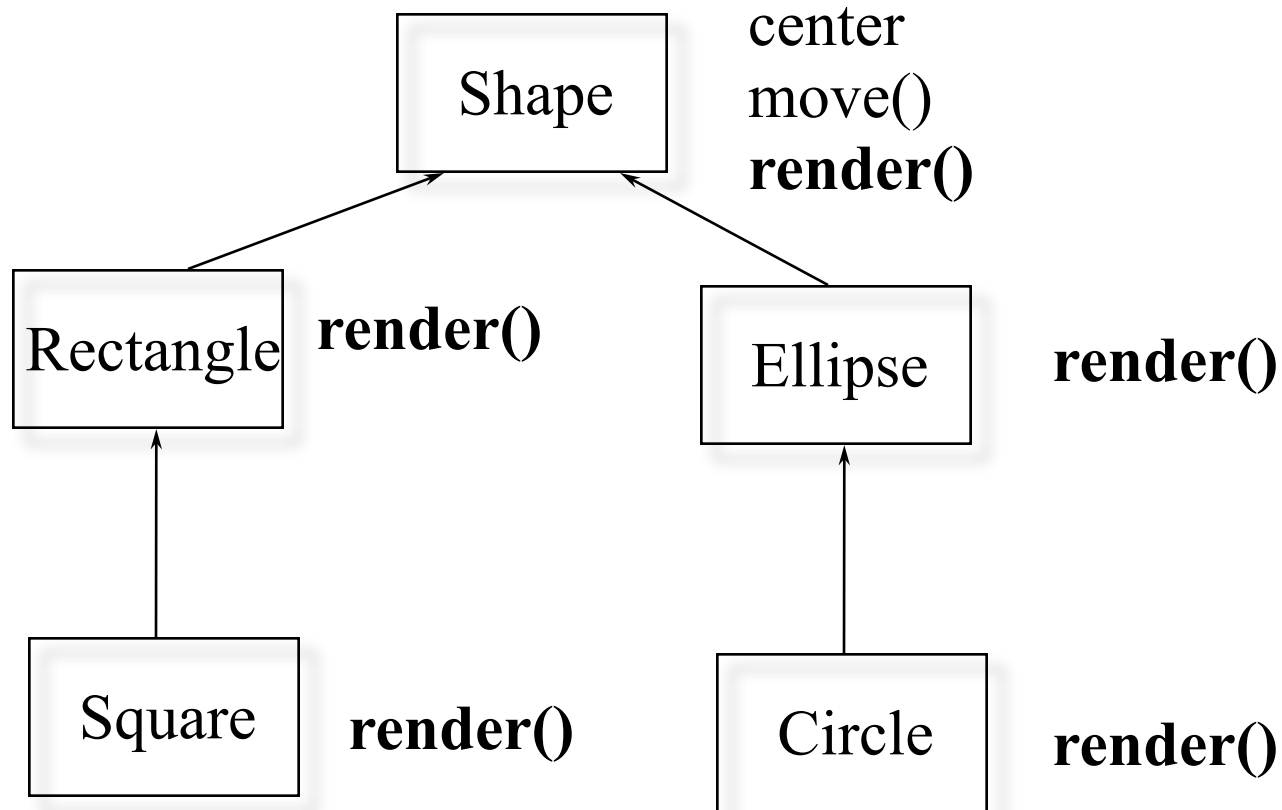

+ center

Inheritance in C++

- Can define one class in terms of another
- Can capture the notion that
 - An ellipse is a shape
 - A circle is a special kind of ellipse
 - A rectangle is a different shape
 - Circles, ellipses, and rectangles share common
 - attributes
 - services
 - Circles, ellipses, and rectangles are not identical

Conceptual model

Note: Deriving Circle from Ellipse is a poor design choice!

In C++

- Define the general properties of a Shape

```
class XYPos{ ... };    // x,y point
class Shape {
public:
    Shape();
    virtual ~Shape();
    virtual void render();
    void move(const XYPos&);
    virtual void resize();
protected:
    XYPos center;
};
```

Polymorphism

- Upcast: take an object of the derived class as an object of the base one.
 - Ellipse can be treated as a Shape
- Dynamic binding:
 - Binding: which function to be called
 - Static binding: call the function as the code
 - Dynamic binding: call the function of the object

Virtual functions

- Non-virtual functions
 - Compiler generates *static*, or direct call to stated type
 - Faster to execute
- Virtual functions
 - Can be *transparently* overridden in a derived class
 - Objects carry a pack of their virtual functions
 - Compiler checks pack and *dynamically* calls the right function
 - If compiler knows the function at compile-time, it can generate a static call

Add new shapes

```
class Ellipse : public Shape {
public:
    Ellipse(float maj, float minr);
    virtual void render(); // will define own
protected:
    float major_axis, minor_axis;
};

class Circle : public Ellipse {
public:
    Circle(float radius) : Ellipse(radius, radius){}
    virtual void render();
};
```

Example

```
void render(Shape* p) {  
    p->render();    // calls correct render function  
}                  // for given Shape!  
  
void func() {  
    Ellipse ell(10, 20);  
    ell.render();    // static -- Ellipse::render();  
  
    Circle circ(40);  
    circ.render();    // static -- Circle::render();  
  
    render(&ell);    // dynamic -- Ellipse::render();  
    render(&circ);    // dynamic -- Circle::render()  
}
```

Abstract base classes

- An *abstract base class* has pure virtual functions
 - Only interface defined
 - No function body given
- *Abstract base classes cannot be instantiated*
 - Must derive a new class (or classes)
 - Must supply definitions for all pure virtuals before class can be instantiated

In C++

- Define the general properties of a Shape

```
class XYPos{ ... };    // x,y point
class Shape {
public:
    Shape();
    virtual void render() = 0; // mark
    render() pure
    void move(const XYPos&);
    virtual void resize();
protected:
    XYPos center;
};
```

Abstract classes

- Why use them?
 - Modeling
 - Force correct behavior
 - Define interface without defining an implementation
- When to use them?
 - Not enough information is available
 - When designing for interface inheritance

Protocol/Interface classes

- Abstract base class with
 - All non-static member functions are *pure* virtual except destructor
 - Virtual destructor with empty body
 - No non-static member variables, inherited or otherwise
 - May contain static members

Example interface

- Unix character device

```
class CDevice {  
public:  
    virtual ~CDevice();  
  
    virtual int read(...)    = 0;  
    virtual int write(...)  = 0;  
    virtual int open(...)   = 0;  
    virtual int close(...)  = 0;  
    virtual int ioctl(...)  = 0;  
};
```
